

A large, multi-story glass and metal structure, likely a greenhouse or a specialized laboratory, is the central focus. It is surrounded by lush green vegetation and purple flowers in the foreground. The sky is bright blue with some light clouds.

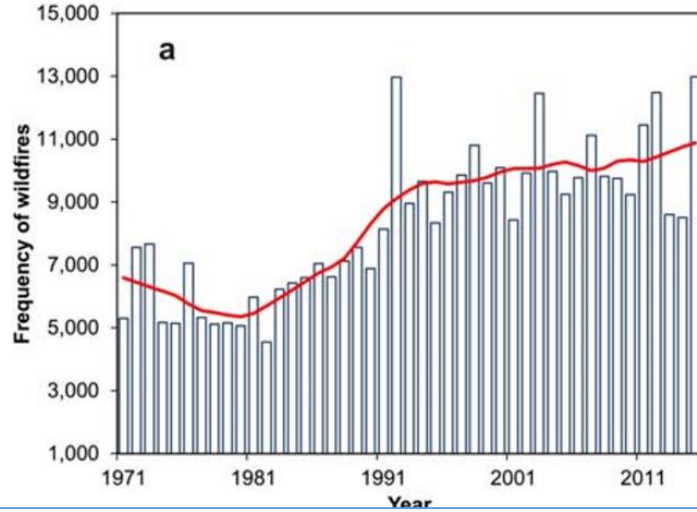

Monitoring and predicting wildfires in Czechia

Marketa Podebradska
podebradska.m@czechglobe.cz

PAST & PRESENT

Rising frequency of wildfire occurrence

Largest recorded wildfire (>1000ha) in 7/2022

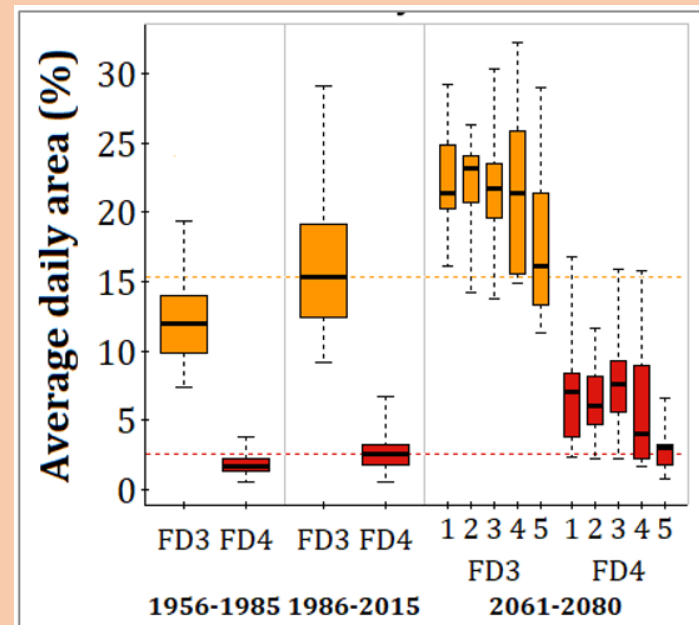

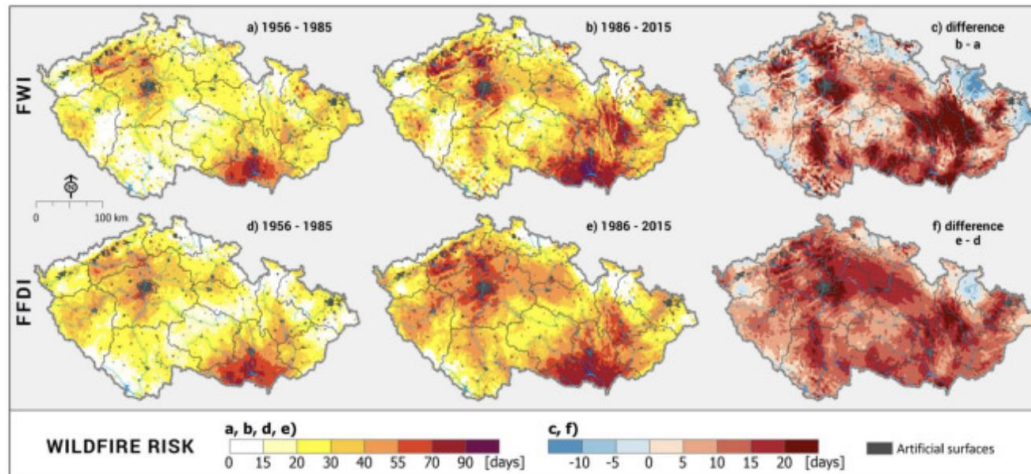

Mozny et al., 2021

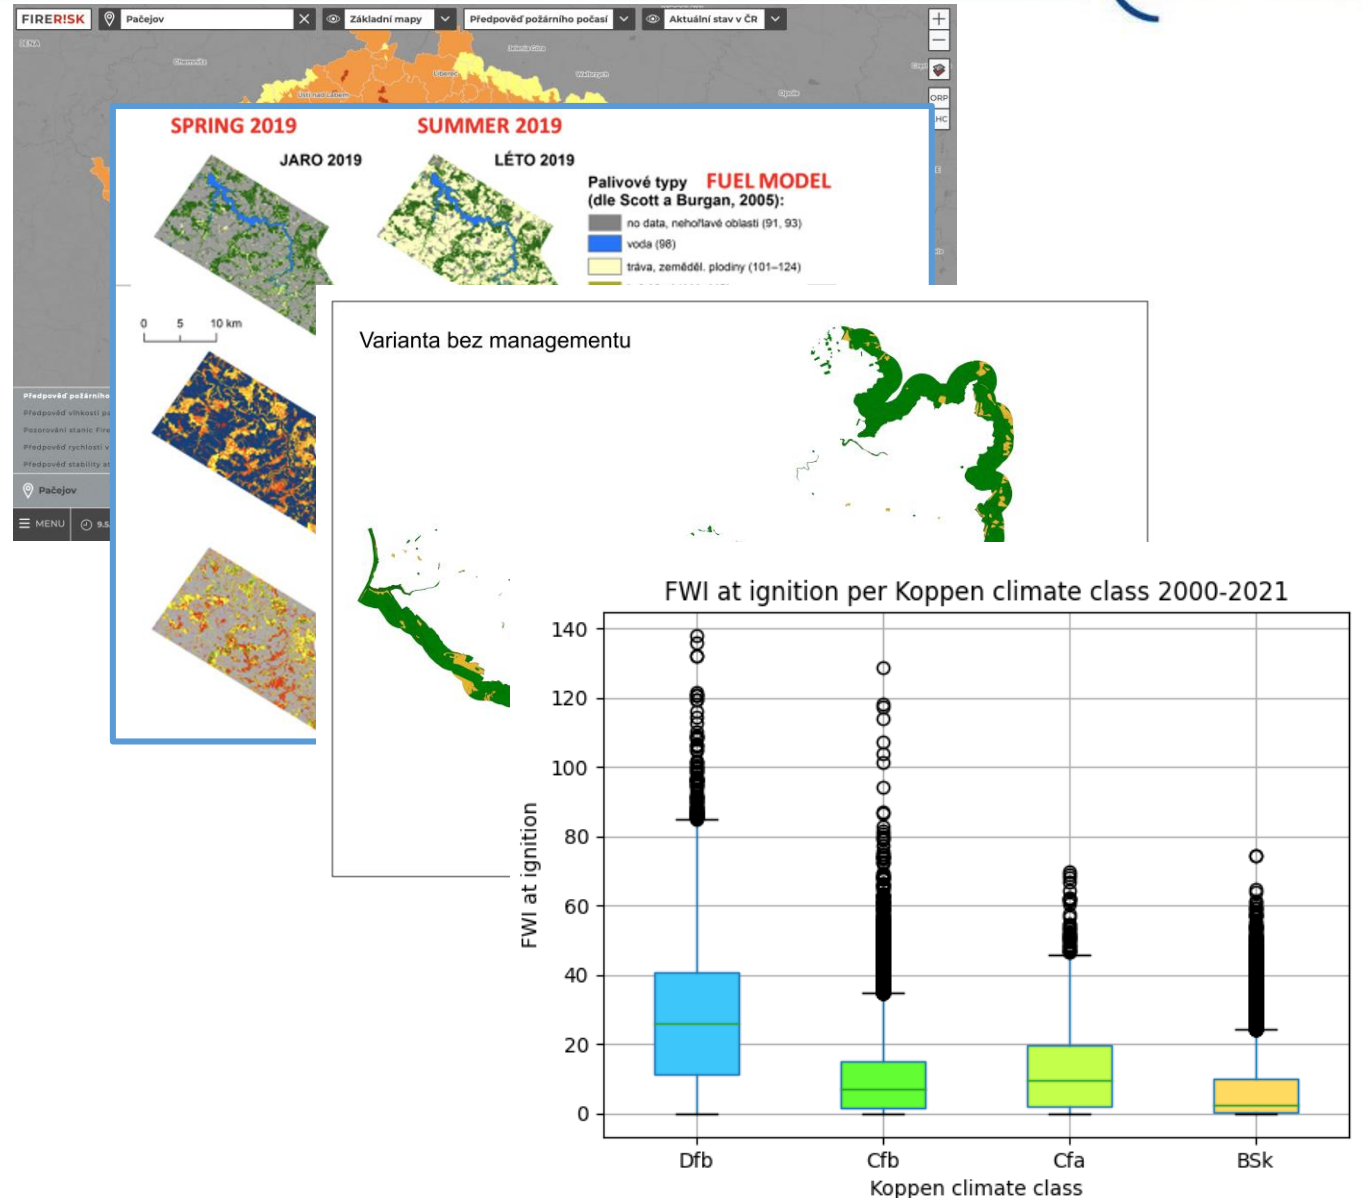

Increasing values of fire weather (up to 20 more days with high values)

FUTURE

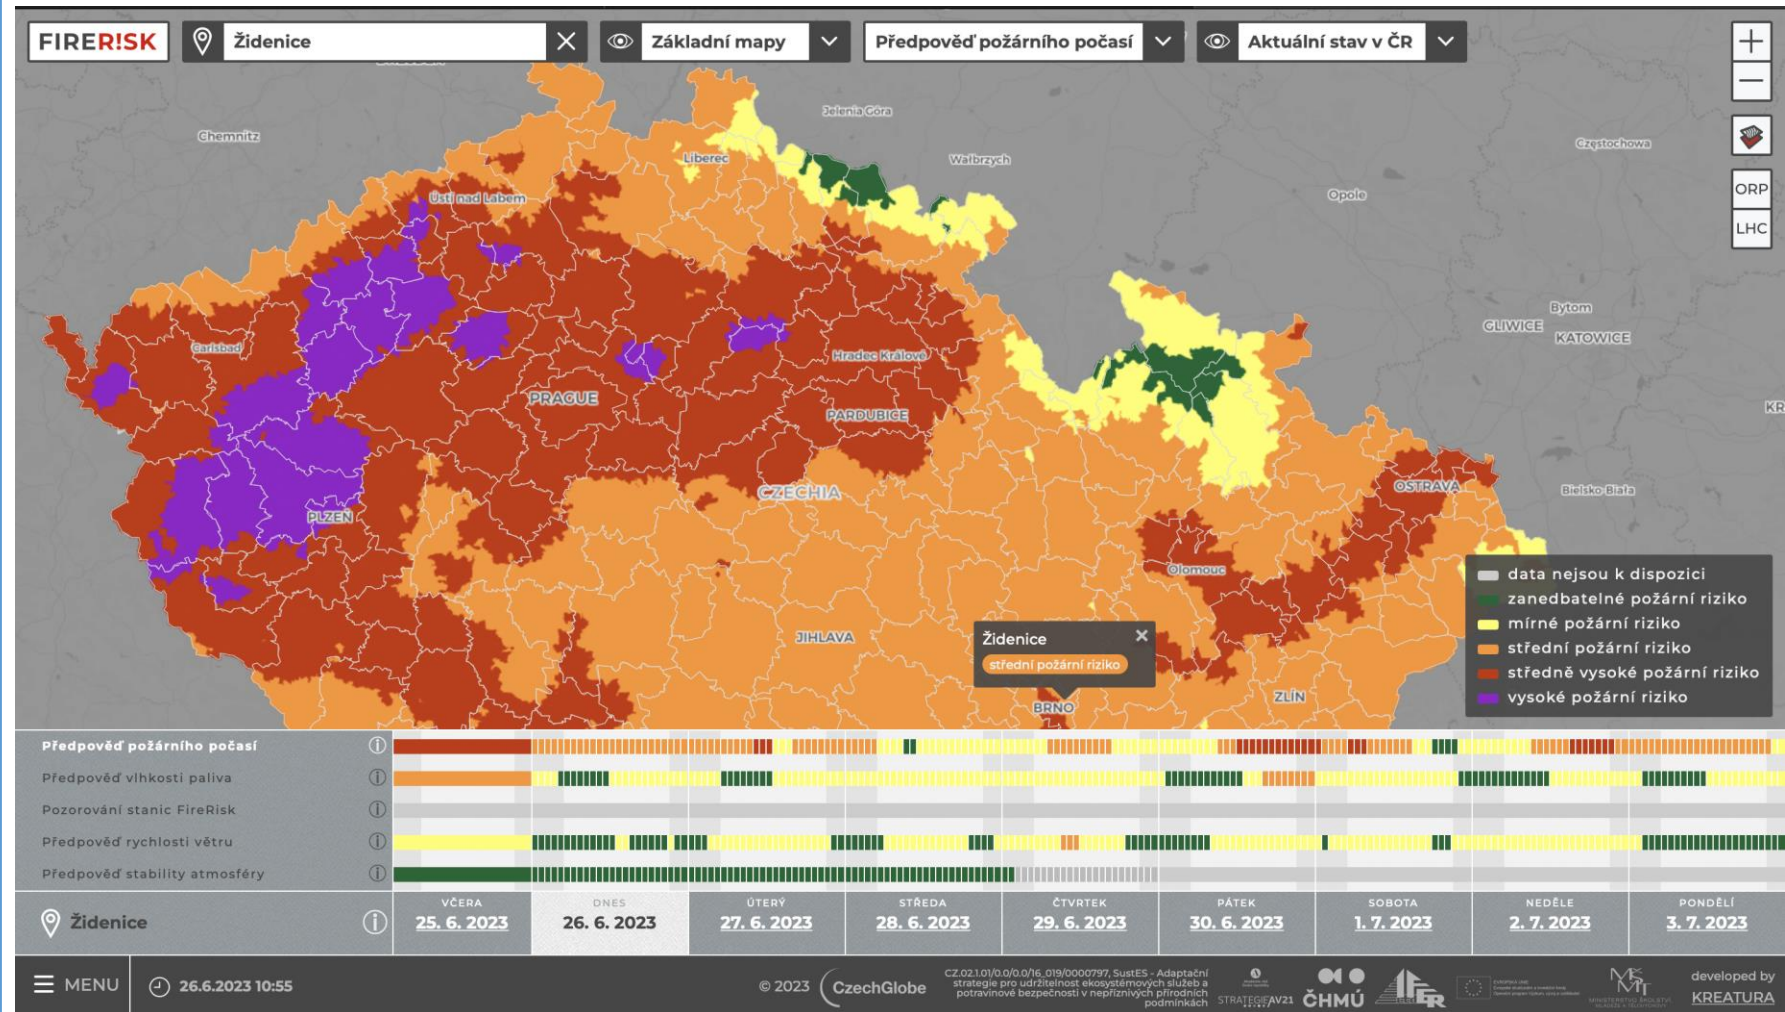

More area affected by conducive fire weather

- Operational wildfire danger monitoring and prediction
- Wildfire behavior modelling – Bohemian Switzerland case study/validation
- Landscape wildfire susceptibility index – collaboration with Institute of Forest Ecology Research
- Future occurrence of large wildfires – climate analogues

- Hourly calculation of FWI and FFDI at 500m
- Daily values correspond to max hourly values
- Median of FWI and FFDI per cadaster
- Worse of the two indices is taken as a resulting value
- Monitoring – updated 4 times a day – combination of multiple forecasting models

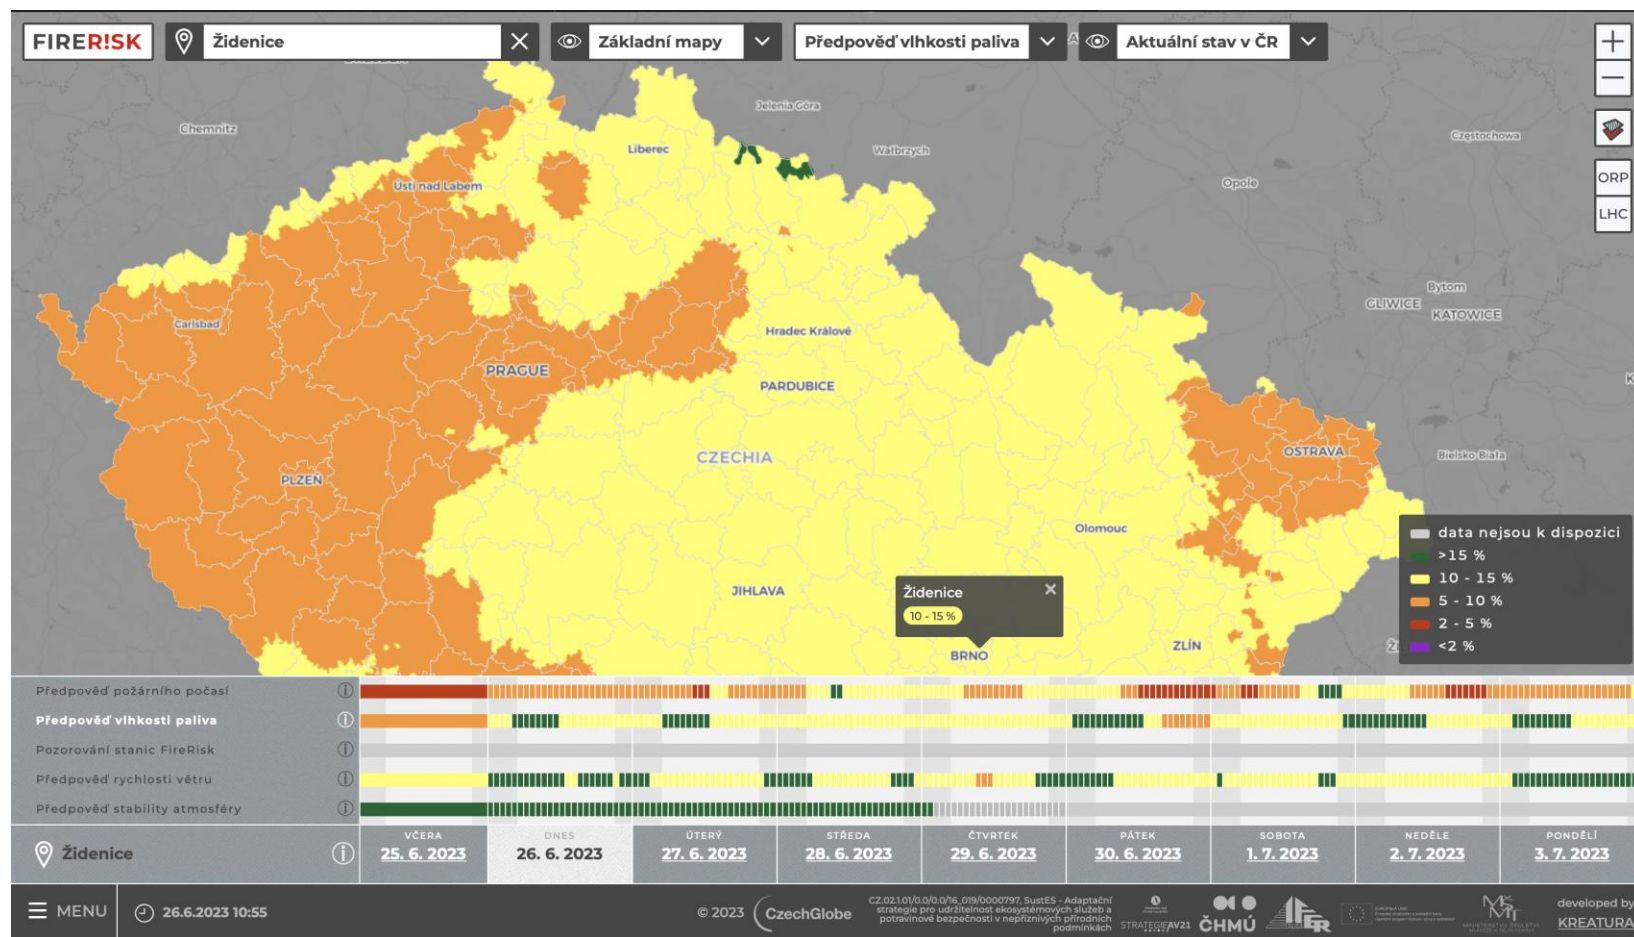

Fuel moisture calculation

- Calculation based on meteorological variables (temperature, relative humidity)
- Correction based on snow cover and sum of precipitation
- Prediction based on the same input as fire weather

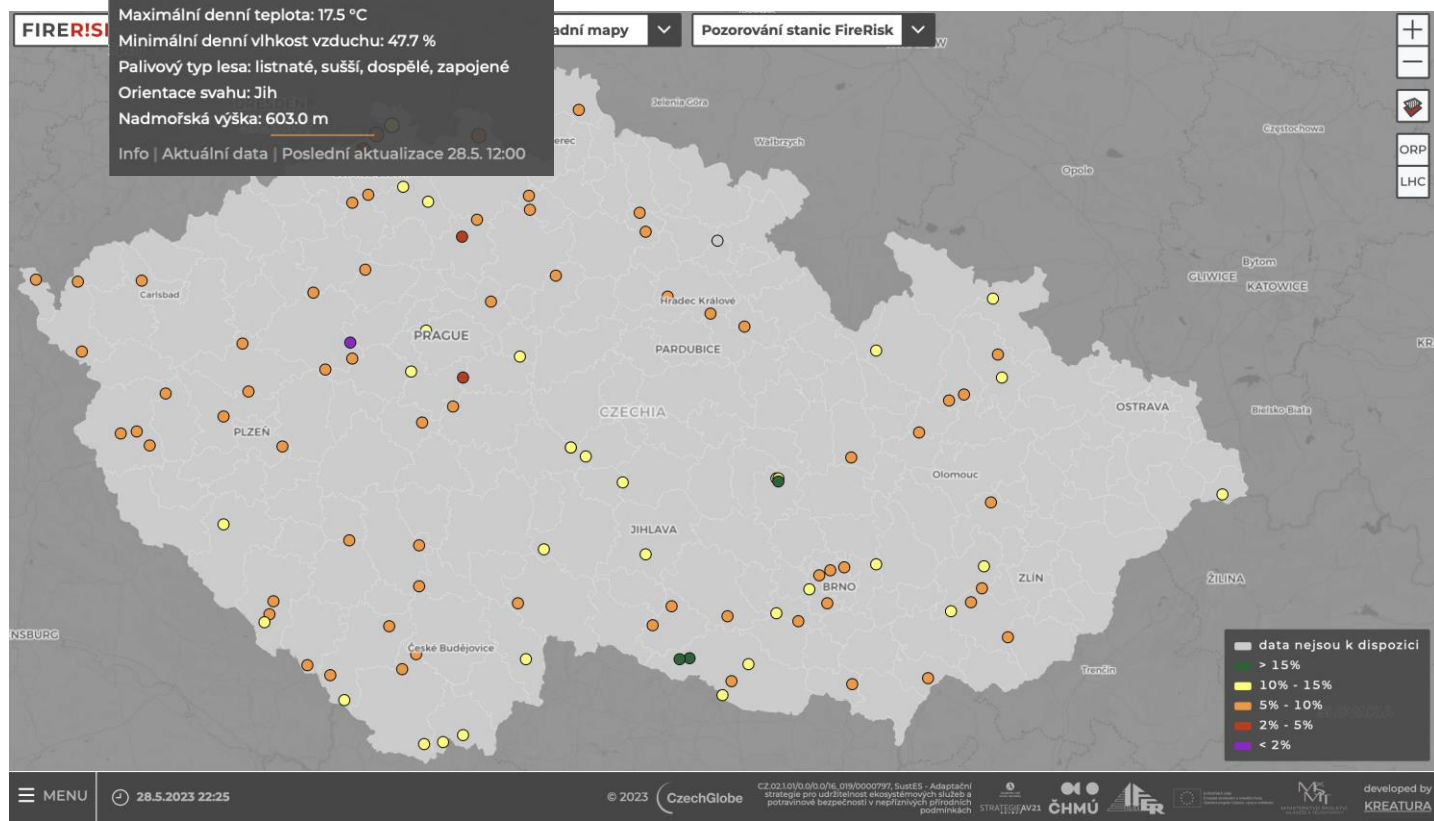

©The COMET Program

Fuel moisture measurements

- A network of stations located at various at-risk locations
- 10-hr fuel moisture measurements
- + dendrometers, soil moisture, air temperature and humidity
- Measuring since last year (1 fire season on record)

Clim4Cast – Central European project

Improving forecasts of extreme weather events

Climate change increases the risk of severe weather events in central Europe. Increasing resilience to droughts, heatwaves and fires is urgent but tools that monitor and predict these phenomena are widely missing. The Clim4Cast project establishes a new weather forecast tool, which will be integrated into existing national monitoring platforms of seven countries. Concrete action plans to set up regional response mechanisms are also developed.

Wildfire behavior modelling

7/2022 - the largest wildfire in CZ (1000ha)

- NP Bohemian Switzerland
- Complex terrain, bark beetle kill areas, WUI areas
- Big media and public attention
- Fall 2022 - visiting USDA FS Fire Sciences Lab to calibrate FlamMap (FarSite) to Czech conditions
- Objective: recreate observed wildfire behavior and perimeter

FarSite - recreating observed wildfire behavior

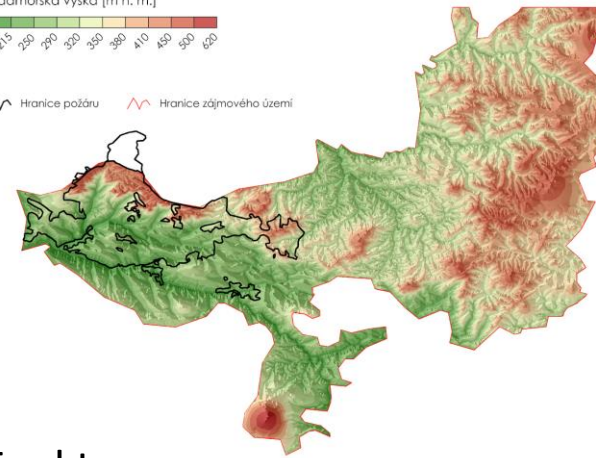

- 8 geospatial layers at 5m resolution – elevation, slope, aspect, fuel type, canopy cover, stand height, crown base height, crown bulk density
- Development of crown parameters (CC, SH, CBH, CBD)
 - LiDAR data + expert knowledge
 - No existing accessible in-situ observations
- Investigating possible weather data sources and their adjustments – station data vs. modeled data – what station best represents the conditions?

FarSite - recreating observed wildfire behavior

FarSite – influence of weather and climate

FarSite – influence of vegetation

A large, multi-story glass and metal greenhouse structure, likely used for climate change research, situated in a lush green environment with ferns and purple flowers in the foreground. The structure is composed of a complex metal frame with large glass panels. The background shows a clear blue sky and some evergreen trees.
